

# Probabilistic And Stochastic UML Statecharts

---

Speaker: Abdallah Salim

Tutor: Dr. David N. Jansen

---

Chair for Software Modeling and Verification  
RWTH Aachen, Germany  
SS 2007

# Overview

## An introduction to Statecharts

- ⦿ Stocharts
- ⦿ Syntax
- ⦿ Semantics
- ⦿ Case Study: A Beverages dispenser
- ⦿ Conclusion

# The UML perspective - A scenario

Name: Mr Troy aka Mr T

Age: 29

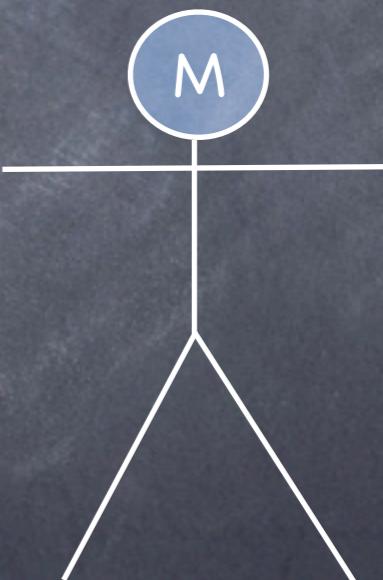

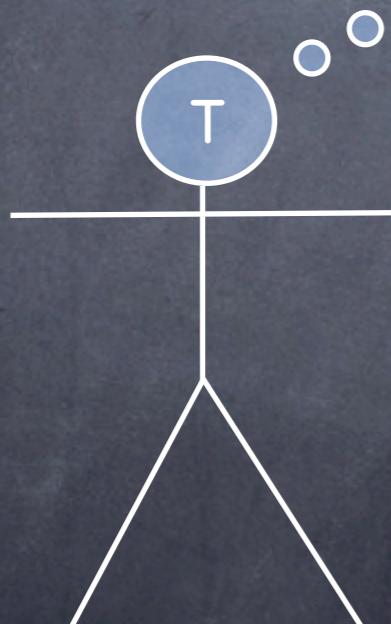

Position: Software Engineer

Name: Mr McNamara aka Mr M

Age: 27

Position: Visual designer

T seems to have an idea !

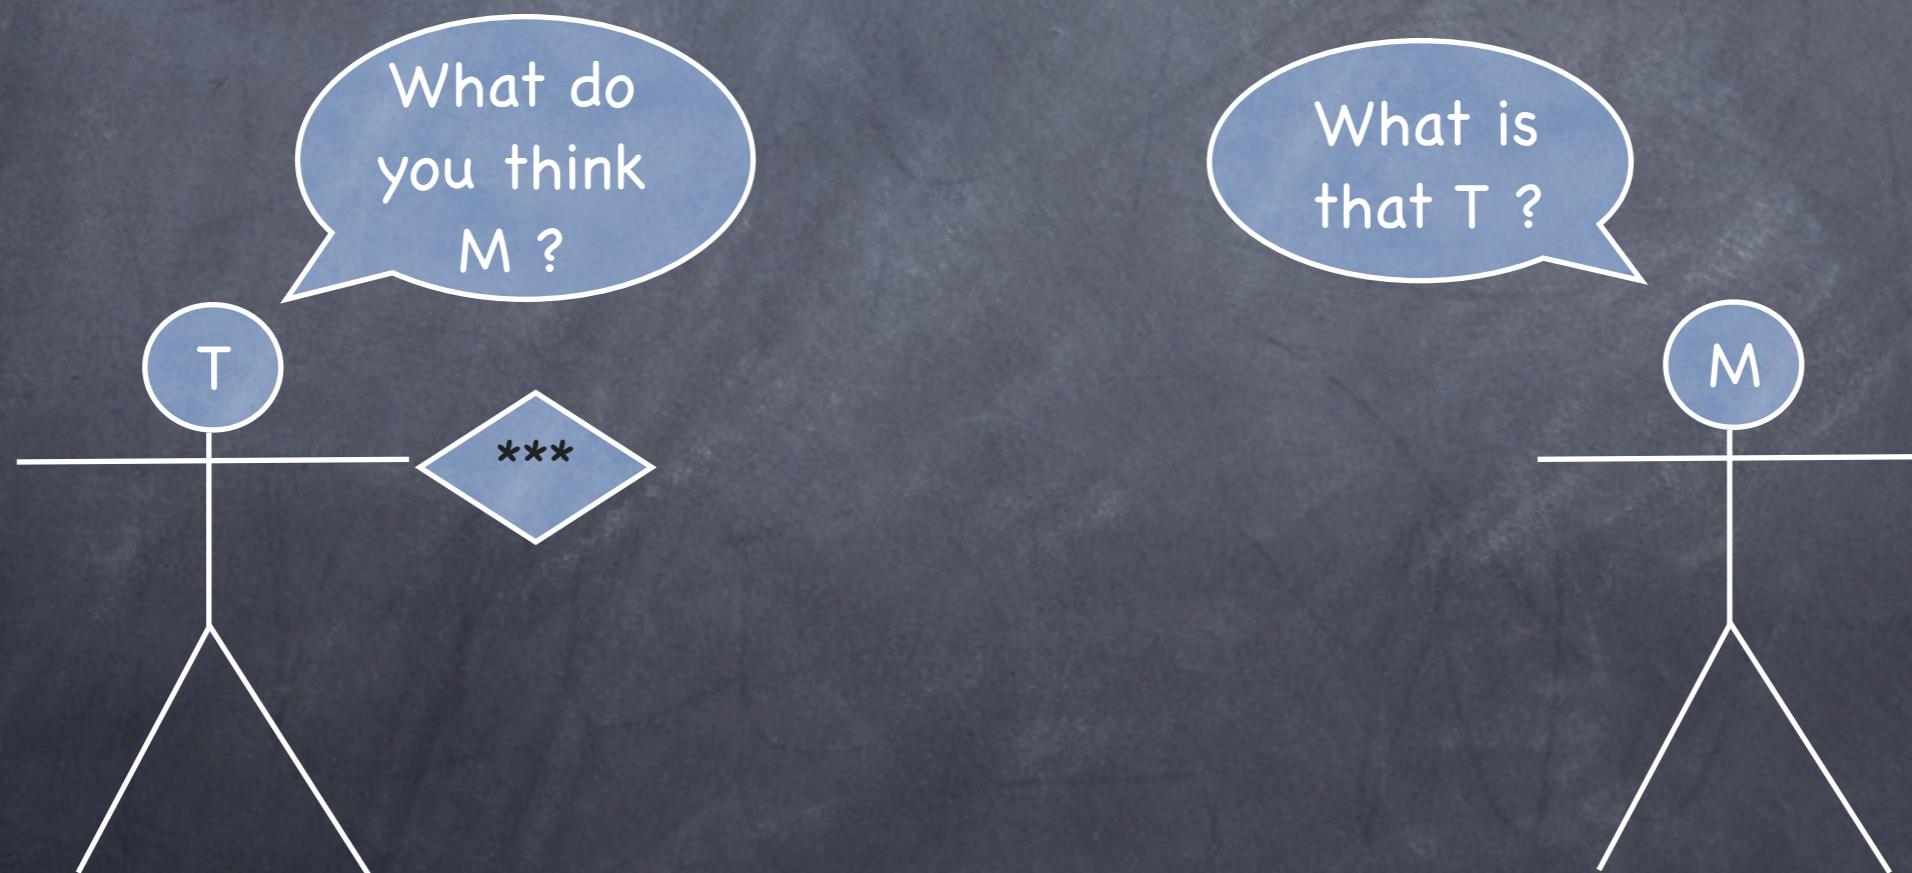

# The UML perspective - Getting the message across

Mr. T has a great  
design idea

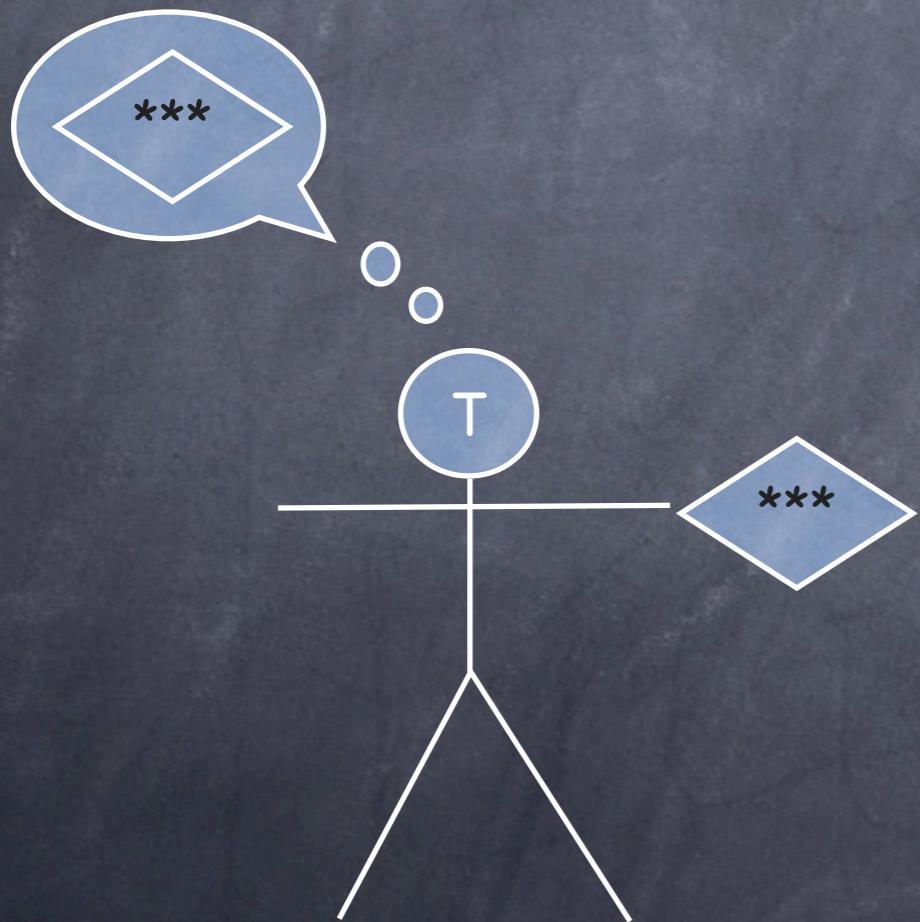

but ...

Mr. M doesn't seem to  
understand T's design

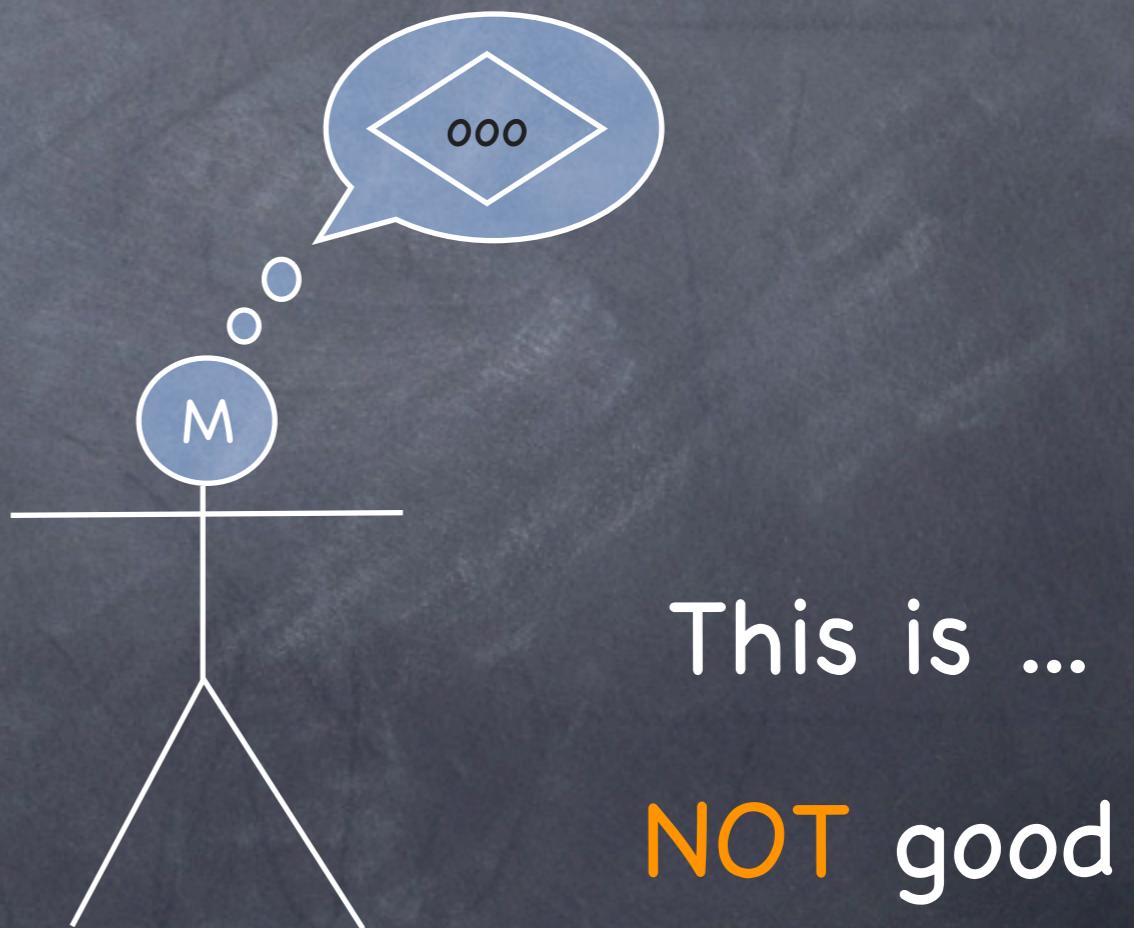

# The UML perspective - The Problem

Mr. T has an idea in  
his head

but ...

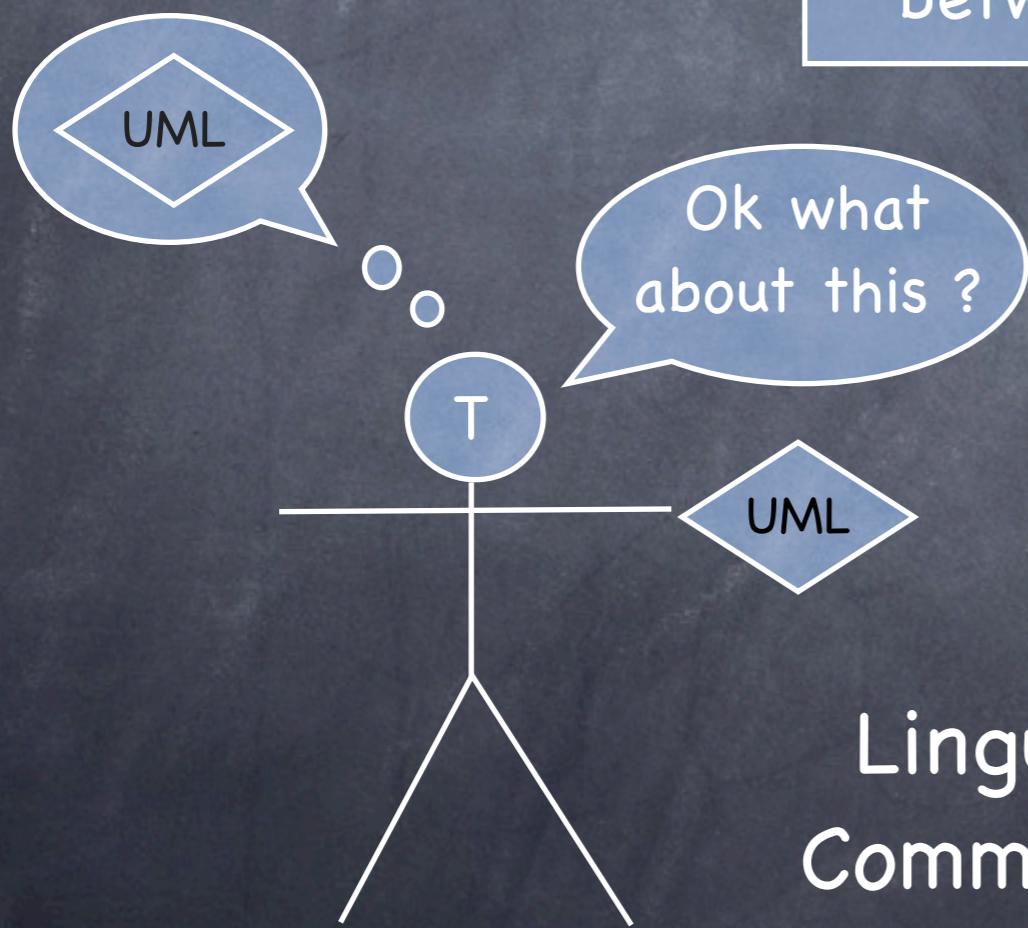

Mr. M forms a  
completely **different**  
one in his head

This is ...  
**NOT** good

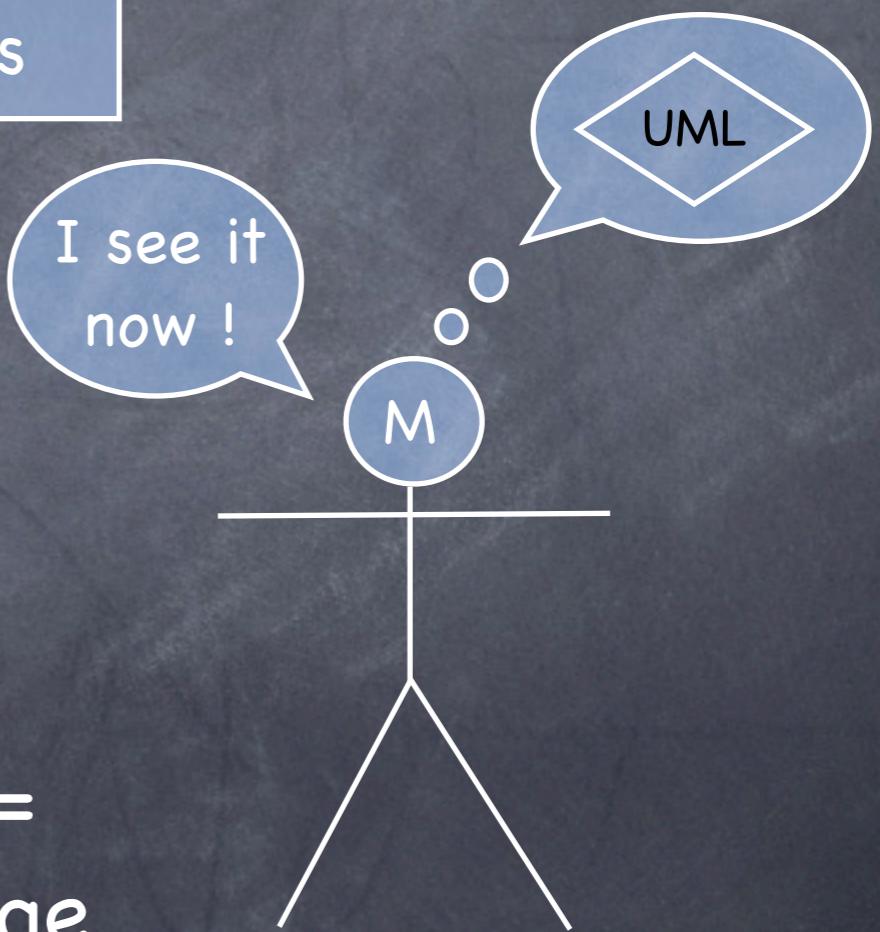

# The UML perspective - Enter UML

Mr. T redesigns with UML....

Why does Mr M get it ?  
UML provides a Lingua franca that promotes communication between designers

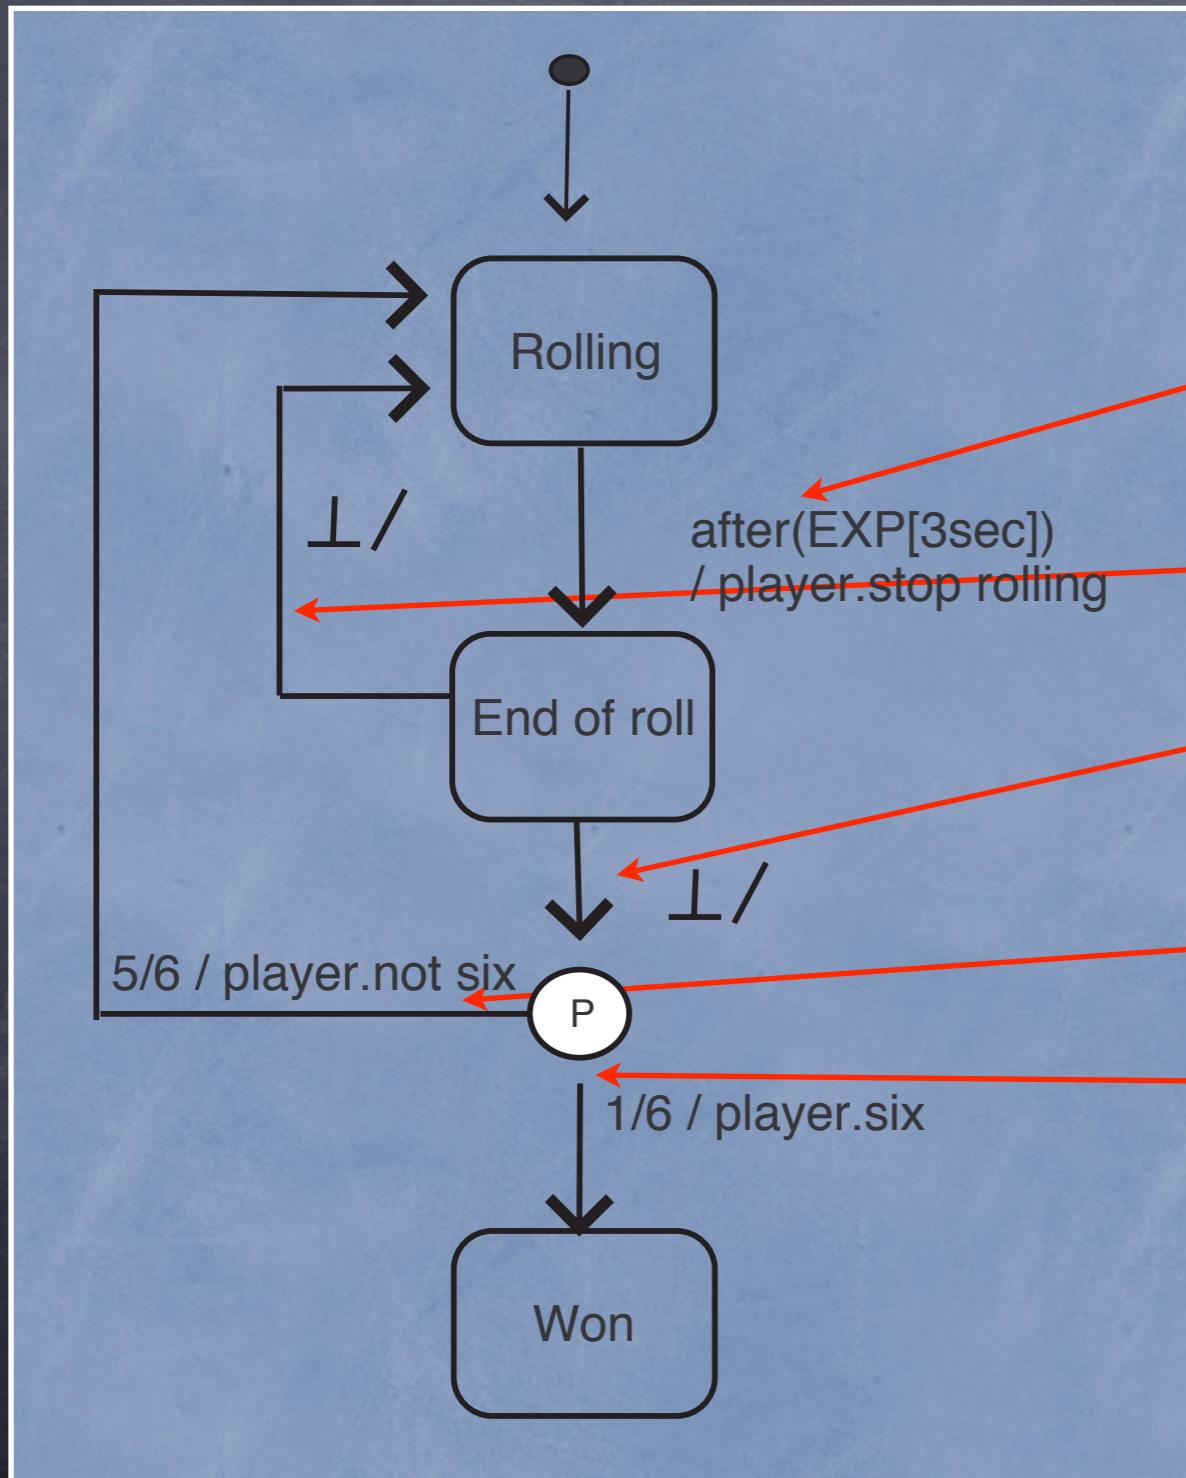

Mr. M gets it !!!

Lingua franca = Common Language

# Introducing StoCharts - An Intuition

StoChart Example: 6 wins the game

(1) Dice starts rolling  
(takes **some** time to stop:  
3 sec)

(2) Nondeterministic choice  
- Dice **cannot** be read  
- Dice **can** be read

(3) Probabilistic choice  
-  $\{1,2,3,4,5\}$  face-up  
(start rolling again)  
- 6 face-up  
(game over)

$\perp$  : No need to wait to take edge

## Some Distinctions – Probabilistic choice

(Example: Throwing a fair coin)

Probabilistic choice:

It is not clear which possibility out of a discrete set a system may take.

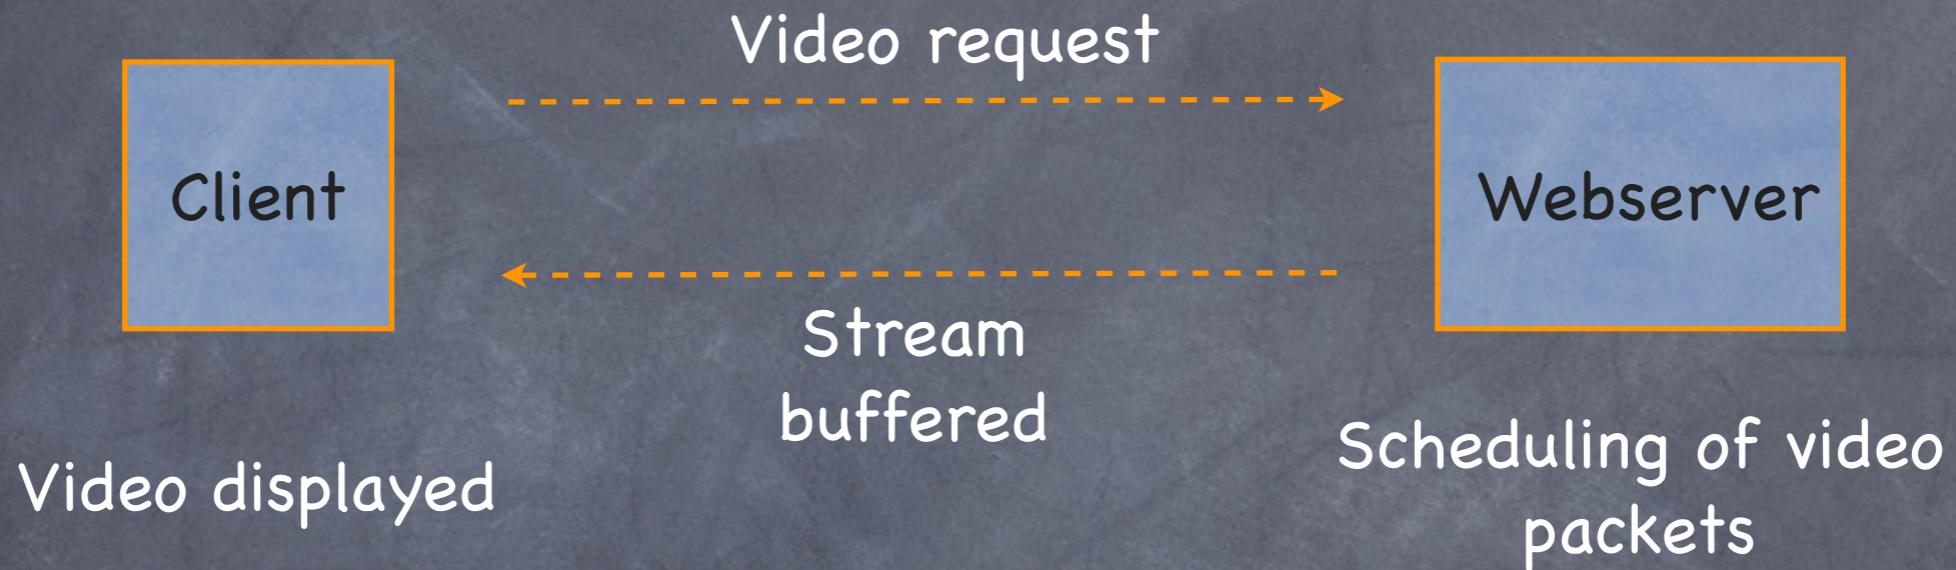

So what does “not clear” mean ?

- Prediction: 50% of the time heads/tails will occur.
- BUT impossible to predict the actual outcome for each toss i.e., whether it's a head or a tail.

# Some Distinctions – Stochastic timing

(Example: Video Streaming)

Stochastic timing ?

- Some time needed to schedule video packets (server).
- Some time for video to be displayed (client).

# Some Distinctions - Probabilistic vs (non) deterministic Phenomena

Probabilistic (Examples: Weather predictions - Probability of rain, snow etc; Rolling of dice in a board game)

Deterministic (Example: Forced moves in chess)

Nondeterministic (Examples: Free moves in chess and Tic Tac Toe)

## Some Distinctions - Non/Not determinism

### Nondeterministic <> Not deterministic

Not deterministic Phenomena

Only infers that a phenomenon is either probabilistic or nondeterministic (and nothing more !!)

An unfortunate terminology but one we have to live with :-(

# Some Distinctions - System vs Environment randomness

## Environment randomness

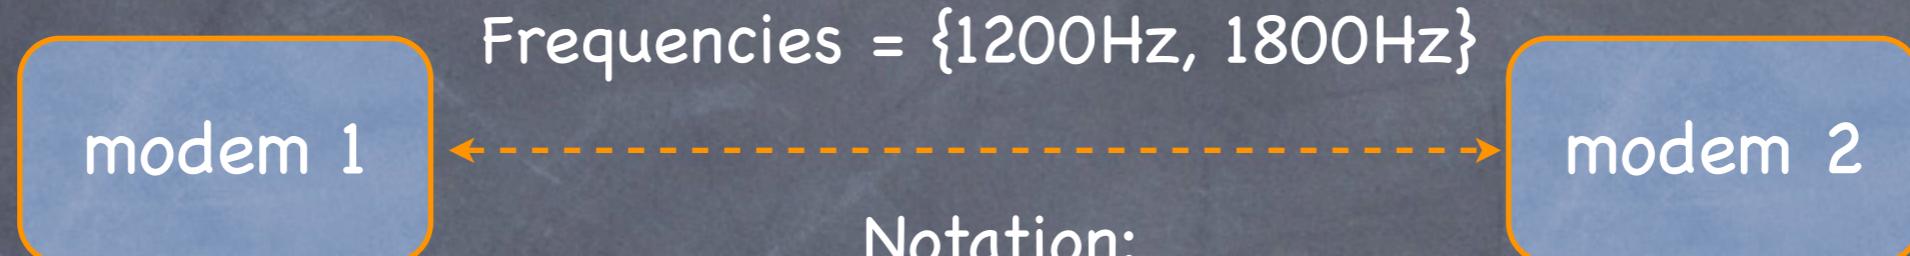

Environment randomness (Example: Reactive system - Bank ATM, Dispenser, etc)

Intuition: System exposed to external random stimuli and reacts.

System reaction is **NOT** random

## Some Distinctions - System randomness

Requirement : Modems must transmit on different frequencies

-  $H_j$  : “Heads” for modem  $j$  ( $1 \leq j \leq 2$ )

[Semantics: Modem  $j$  transmits at 1200 Hz]

-  $T_j$  : “Tails” for modem  $j$  ( $1 \leq j \leq 2$ )

[Semantics: Modem  $j$  transmits at 1800 Hz]

(1) Throw a coin.

Randomised

(2) (i) Heads  $\Rightarrow$  Transmit at 1200 Hz.

Algorithm

(ii) Tails  $\Rightarrow$  Transmit at 1800 Hz.

(modem 1)

(3) No response received (modem 2 using similar frequency) after some time  $\Rightarrow$  goto 1  
else end. (modems using different frequencies)

# Overview

- ⦿ An introduction to Statecharts
- **StoCharts**
  - ⦿ Syntax
  - ⦿ Semantics
- ⦿ Case Study: A Beverages dispenser
- ⦿ Conclusion

# UML Extensions – P-Statecharts & StoCharts

We can extend UML Statecharts: 2 fold Extension

Extension 1: Probabilistic choice

(Example: Heads/Tails choice on a coin toss)

Extension 2: Stochastic timing

(Example: Timing in a Drink dispenser)

Statecharts + Extension 1  
= Probabilistic Statecharts (aka P-Statecharts)

Statecharts + Extension 1 + Extension 2  
= Stochastic Statecharts (aka StoCharts)

# UML Extensions - Random probability distributions

DET [x min]

A deterministic distribution with a duration of x minutes

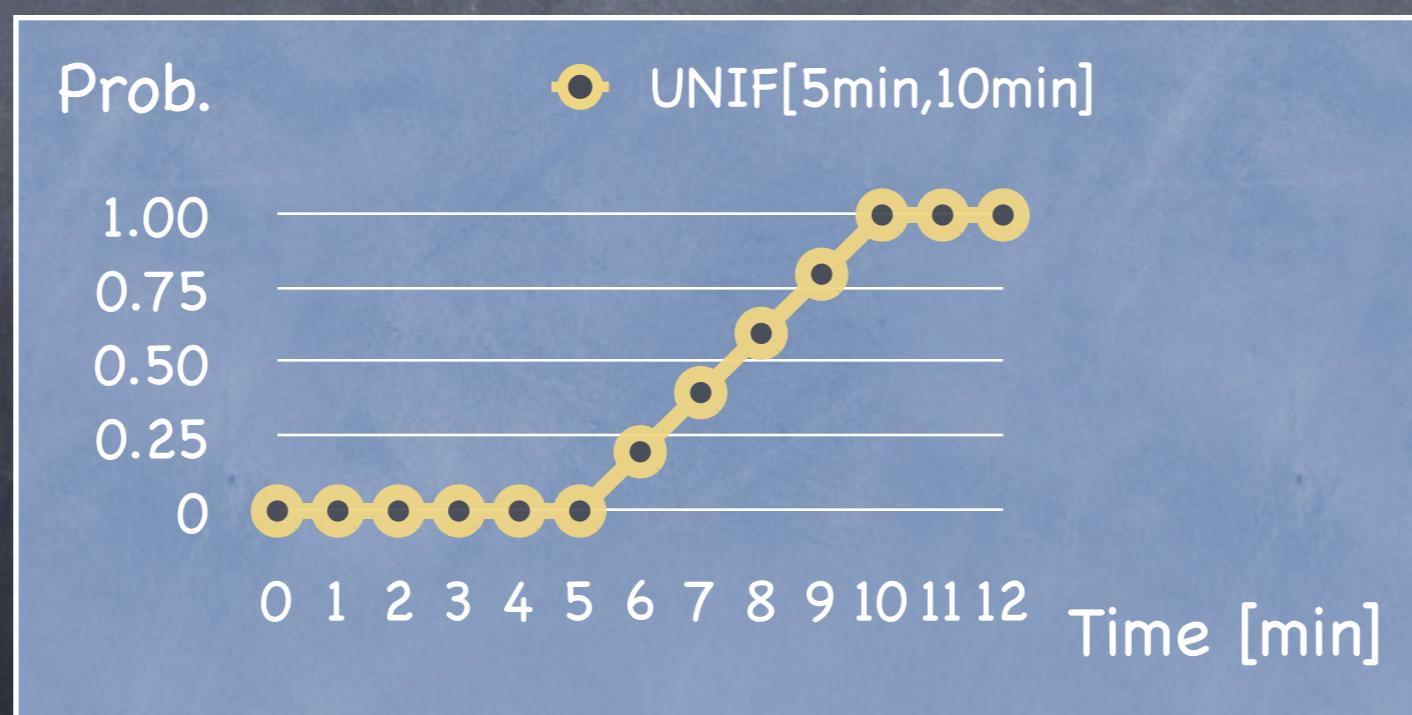

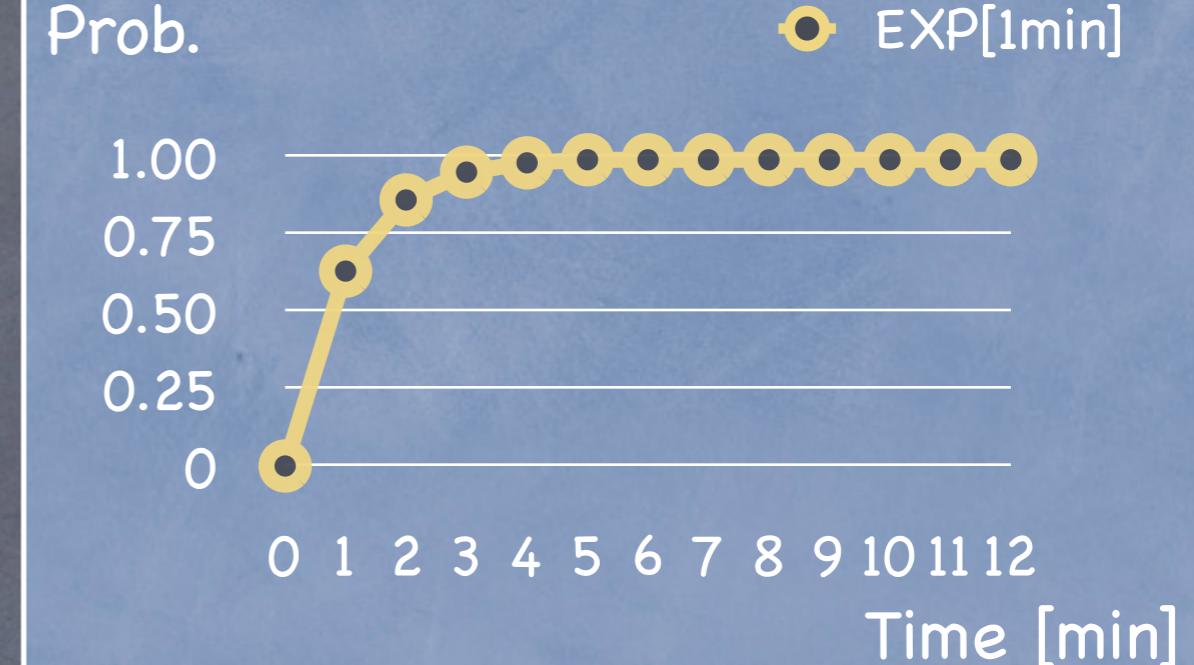

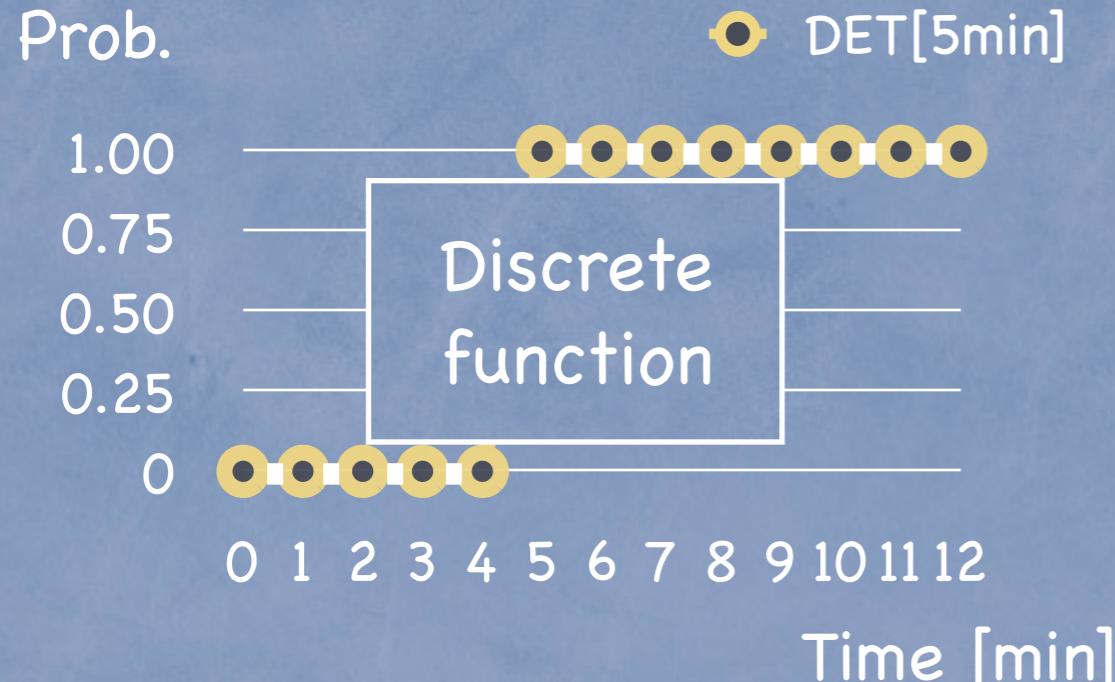

EXP [x min]

A negative exponential distribution with a mean of x minutes

UNIF [x min, y min]

A uniform distribution in the interval from x to y minutes

# UML Extensions - Random probability

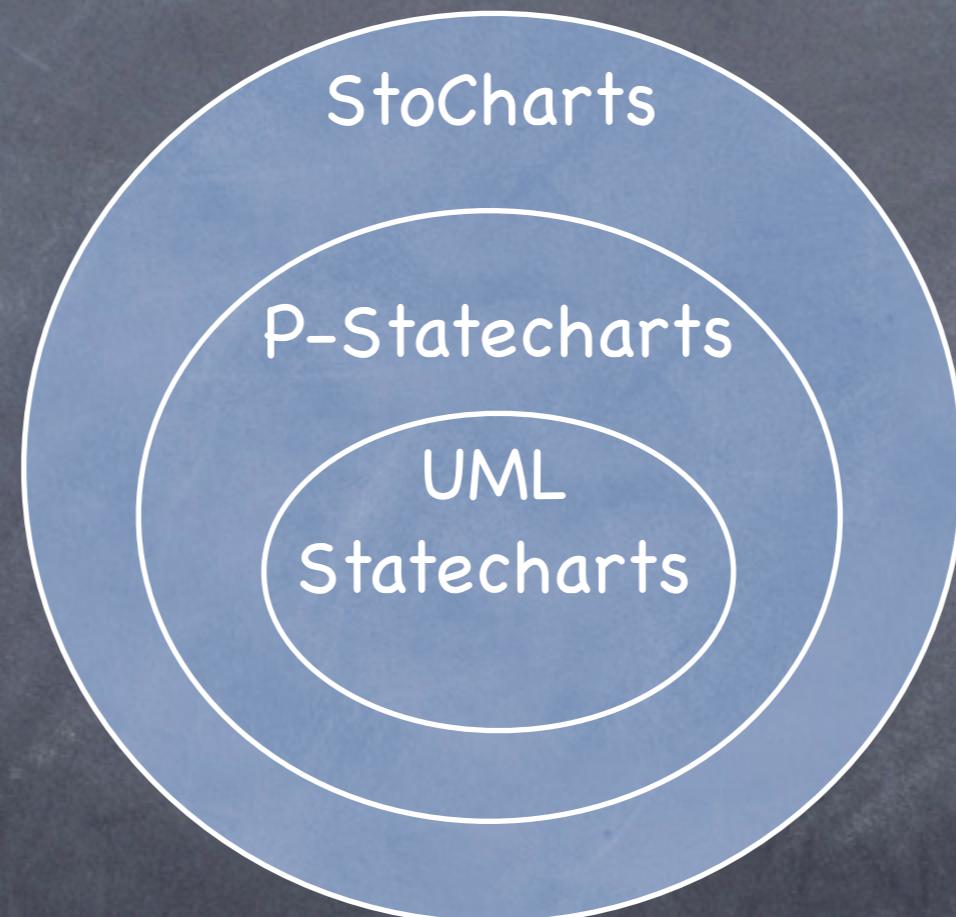

# UML Extensions – Statechart relations

In a nutshell ...

UML Statecharts are  
trivial P-Statecharts

UML Statecharts are  
trivial StoCharts

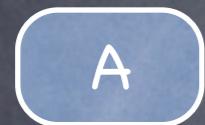

UML Statecharts +  
Probabilistic choice =>  
P-Statecharts

P-Statecharts +  
Stochastic timing =>  
StoCharts

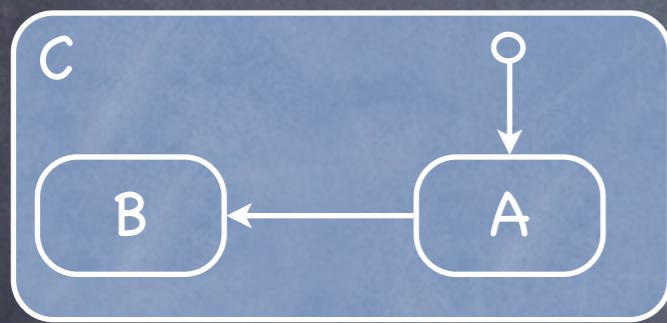

# Overview

# A syntactical perspective - StoChart drawing

Nodes

Parent node C encloses its  
children A, B  
(Default node: A)

F (AND) node partitioned by (OR)  
children A and C  
(Default nodes: B,D)

# A syntactical perspective - StoChart drawing

## Trivial P-edges

$X$  : Set of source nodes  
 $Y$  : set of target nodes  
 $e$  : event  
 $g$  : guard  
 $A$  : action set

Here: Actions "A" have the form (send)  $j.e$  (send event  $e$  to the external component identified by  $j$ )

### Example (Router Login)

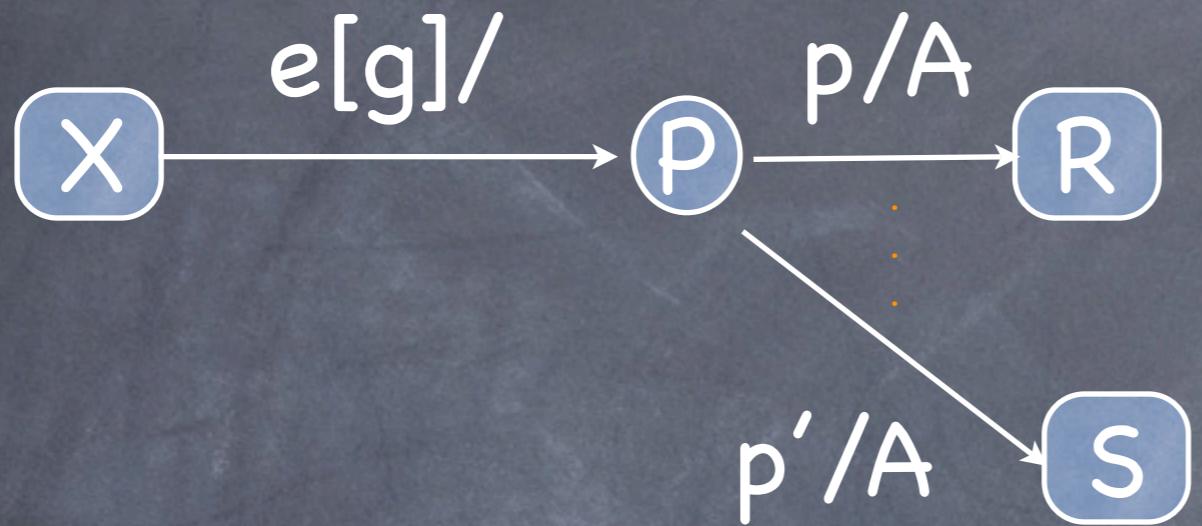

Check password[password="admin"]  
/User.Logged in

Verifying  
User

Showing  
Admin Page

# A syntactical perspective - StoChart drawing

Non trivial P-edges

$X$  : Set of source nodes  
 $Y$  : set of target nodes  
 $e$  : event  
 $g$  : guard  
 $A$  : action set  
 $p, p'$  : Probabilities

$p=p'$  is also possible

Example (File downloading)

## A syntactical perspective - System Perspective

- Intuition: A system is a finite collection of intercommunicating StoCharts
- Formally: Denotable by the set seen below.

$$\{SC_i \mid 1 \leq i \leq n, n \in N\}$$

## A syntactical perspective – StoChart

StoChart 4-Tuple

$$SC_i = (\underline{Nodes}_i, Events_i, Vars_i, PEdges_i)$$

$Nodes_i$

A finite set of nodes structured in a tree

$Events_i$

A finite set of events

$Vars_i$

A finite set of local variables

$PEdges_i$

A finite set of P-edges

## A syntactical perspective – StoChart Events

$$SC_i = (Nodes_i, \underline{Events}_i, Vars_i, PEdges_i)$$

- A finite set of events (Signals that may trigger a state transition)
  - **pseudo event** after( $F$ ) – stochastic random delays
  - $\perp \notin Events_i$  No event is required to trigger a P-edge
  - $PSEvents_i$  Set of Pseudo events

## A syntactical perspective – StoChart Variables

$$SC_i = (Nodes_i, Events_i, \underline{Vars}_i, PEdges_i)$$

- Intuition: A finite set of local variables with an initial value that assigns initial values to variables
- Formally: Denotable by the function below

$$V_0 : Vars_i \rightarrow \mathbb{Z}$$

## A syntactical perspective - StoChart P-edges

P-edge 4-Tuple

$$(X, e, g, P)$$

- A finite set of P-edges
- $X \subseteq \text{Nodes}_i$  A non-empty set of source state nodes
- $e \in \text{Events}_i \cup \text{PSEvents}_i \cup \{\perp\}$  Triggering event that occurs
- $g \in \text{Guards}_i$  A guard existing on the edge
- P denotes the possible actions and target state nodes (formal description needed)

## A syntactical perspective – StoChart P-edges

A formal description of P

$(X, e, g, \underline{P})$

P can be formally described by a probability measure in a discrete probability space

$(\underline{Pow(Action_i)} \times (\underline{Pow(Node_i)} - \{\emptyset\}), P)$

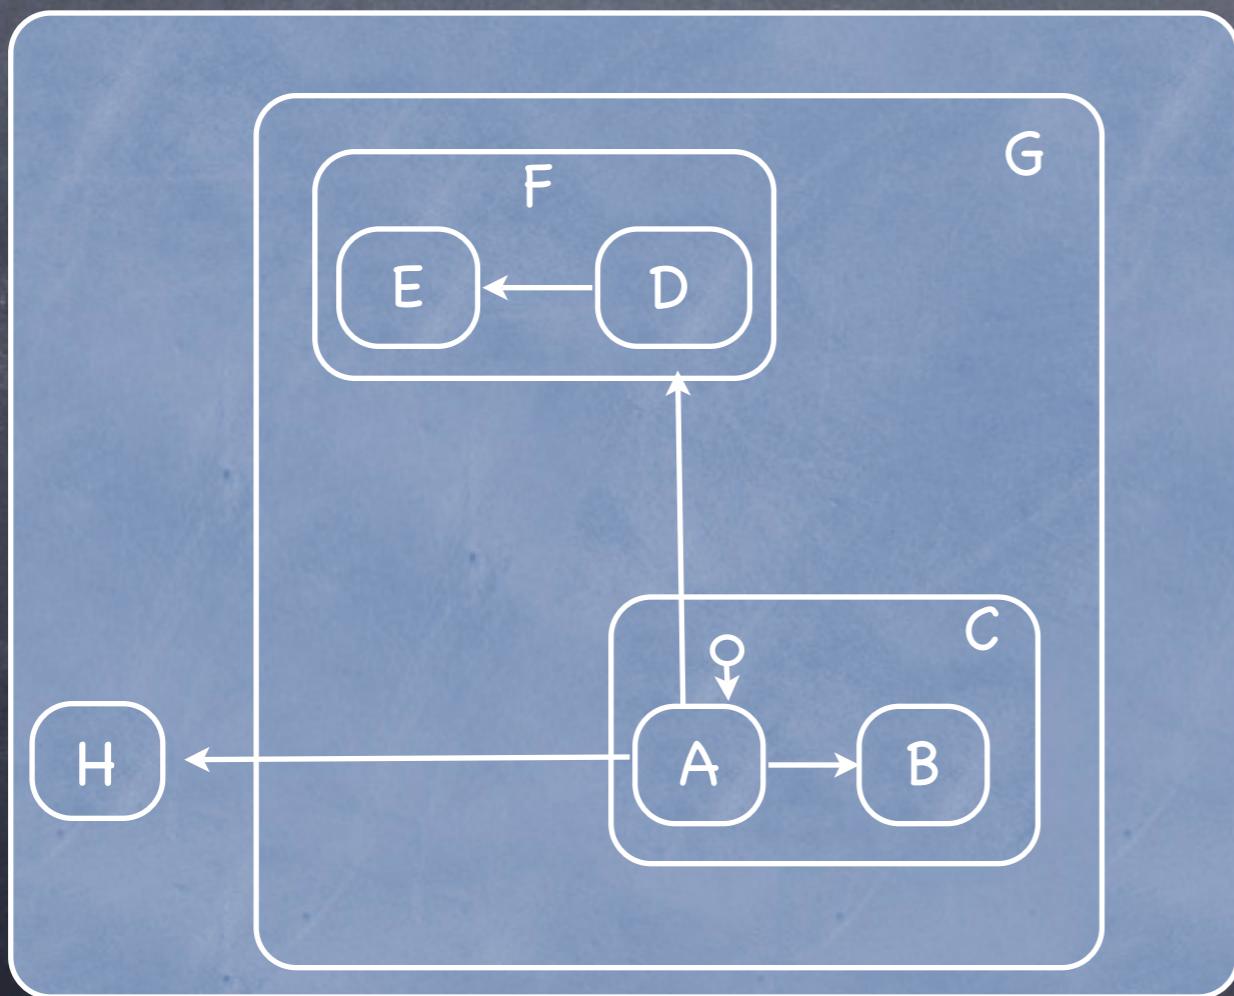

$\Omega$

Denoting the set of possible outcomes

$Pow$ : Denotes a Power set

# A syntactical perspective - StoChart scopes

Intuition: The scope of a P-edge is the smallest (in the parent-child hierarchy) OR-node containing both the source nodes and the target nodes

Scope(A->H) = root  
Scope(A->D) = G  
Scope(A->B) = C

# Overview

# A semantical perspective - Automaton approach

IOSA 7-Tuple

$$(L, \underline{l_0}, T, \underline{A}, I, O, \Delta)$$

IOSA =  
Stochastic I/O-  
Automaton

$L$

A set  $L$  of locations with an initial location

$$l_0 \in L$$

$T$

A set of timers (each possessing a cdf)

$A$

A set of actions partitioned into input-actions  
(from external environment) and output-actions (system intrinsic)

$I$

An input transition relation

$O$

A probabilistic output transition  
relation

$\Delta$

A delay transition relation

# A semantical perspective - Automaton approach

IOSA 7-Tuple

$$(L, l_0, T, A, \underline{I}, O, \Delta)$$

$I$

An input transition relation

$$I : L \times A^{in} \rightarrow L$$

# A semantical perspective - Automaton approach

IOSA 7-Tuple

$$(L, l_0, T, A, I, \underline{O}, \Delta)$$

$O$

A probabilistic output transition relation

$$O \subseteq L \times P(A^{out} \times \text{Pow}(T) \times L)$$

# A semantical perspective - Automaton approach

IOSA 7-Tuple

$$(L, l_0, T, A, I, O, \underline{\Delta})$$

$$\Delta$$

A delay transition relation

$$\Delta \subseteq L \times T \times L$$

# A semantical perspective - Enabled Transitions

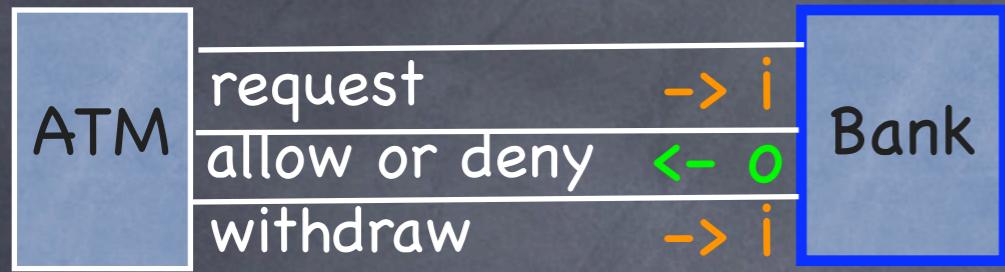

IOSA 7-Tuple

$$(L, l_0, T, A, I, O, \Delta)$$

*o*: output transition  
*i*: input transition  
*d*: delay transition

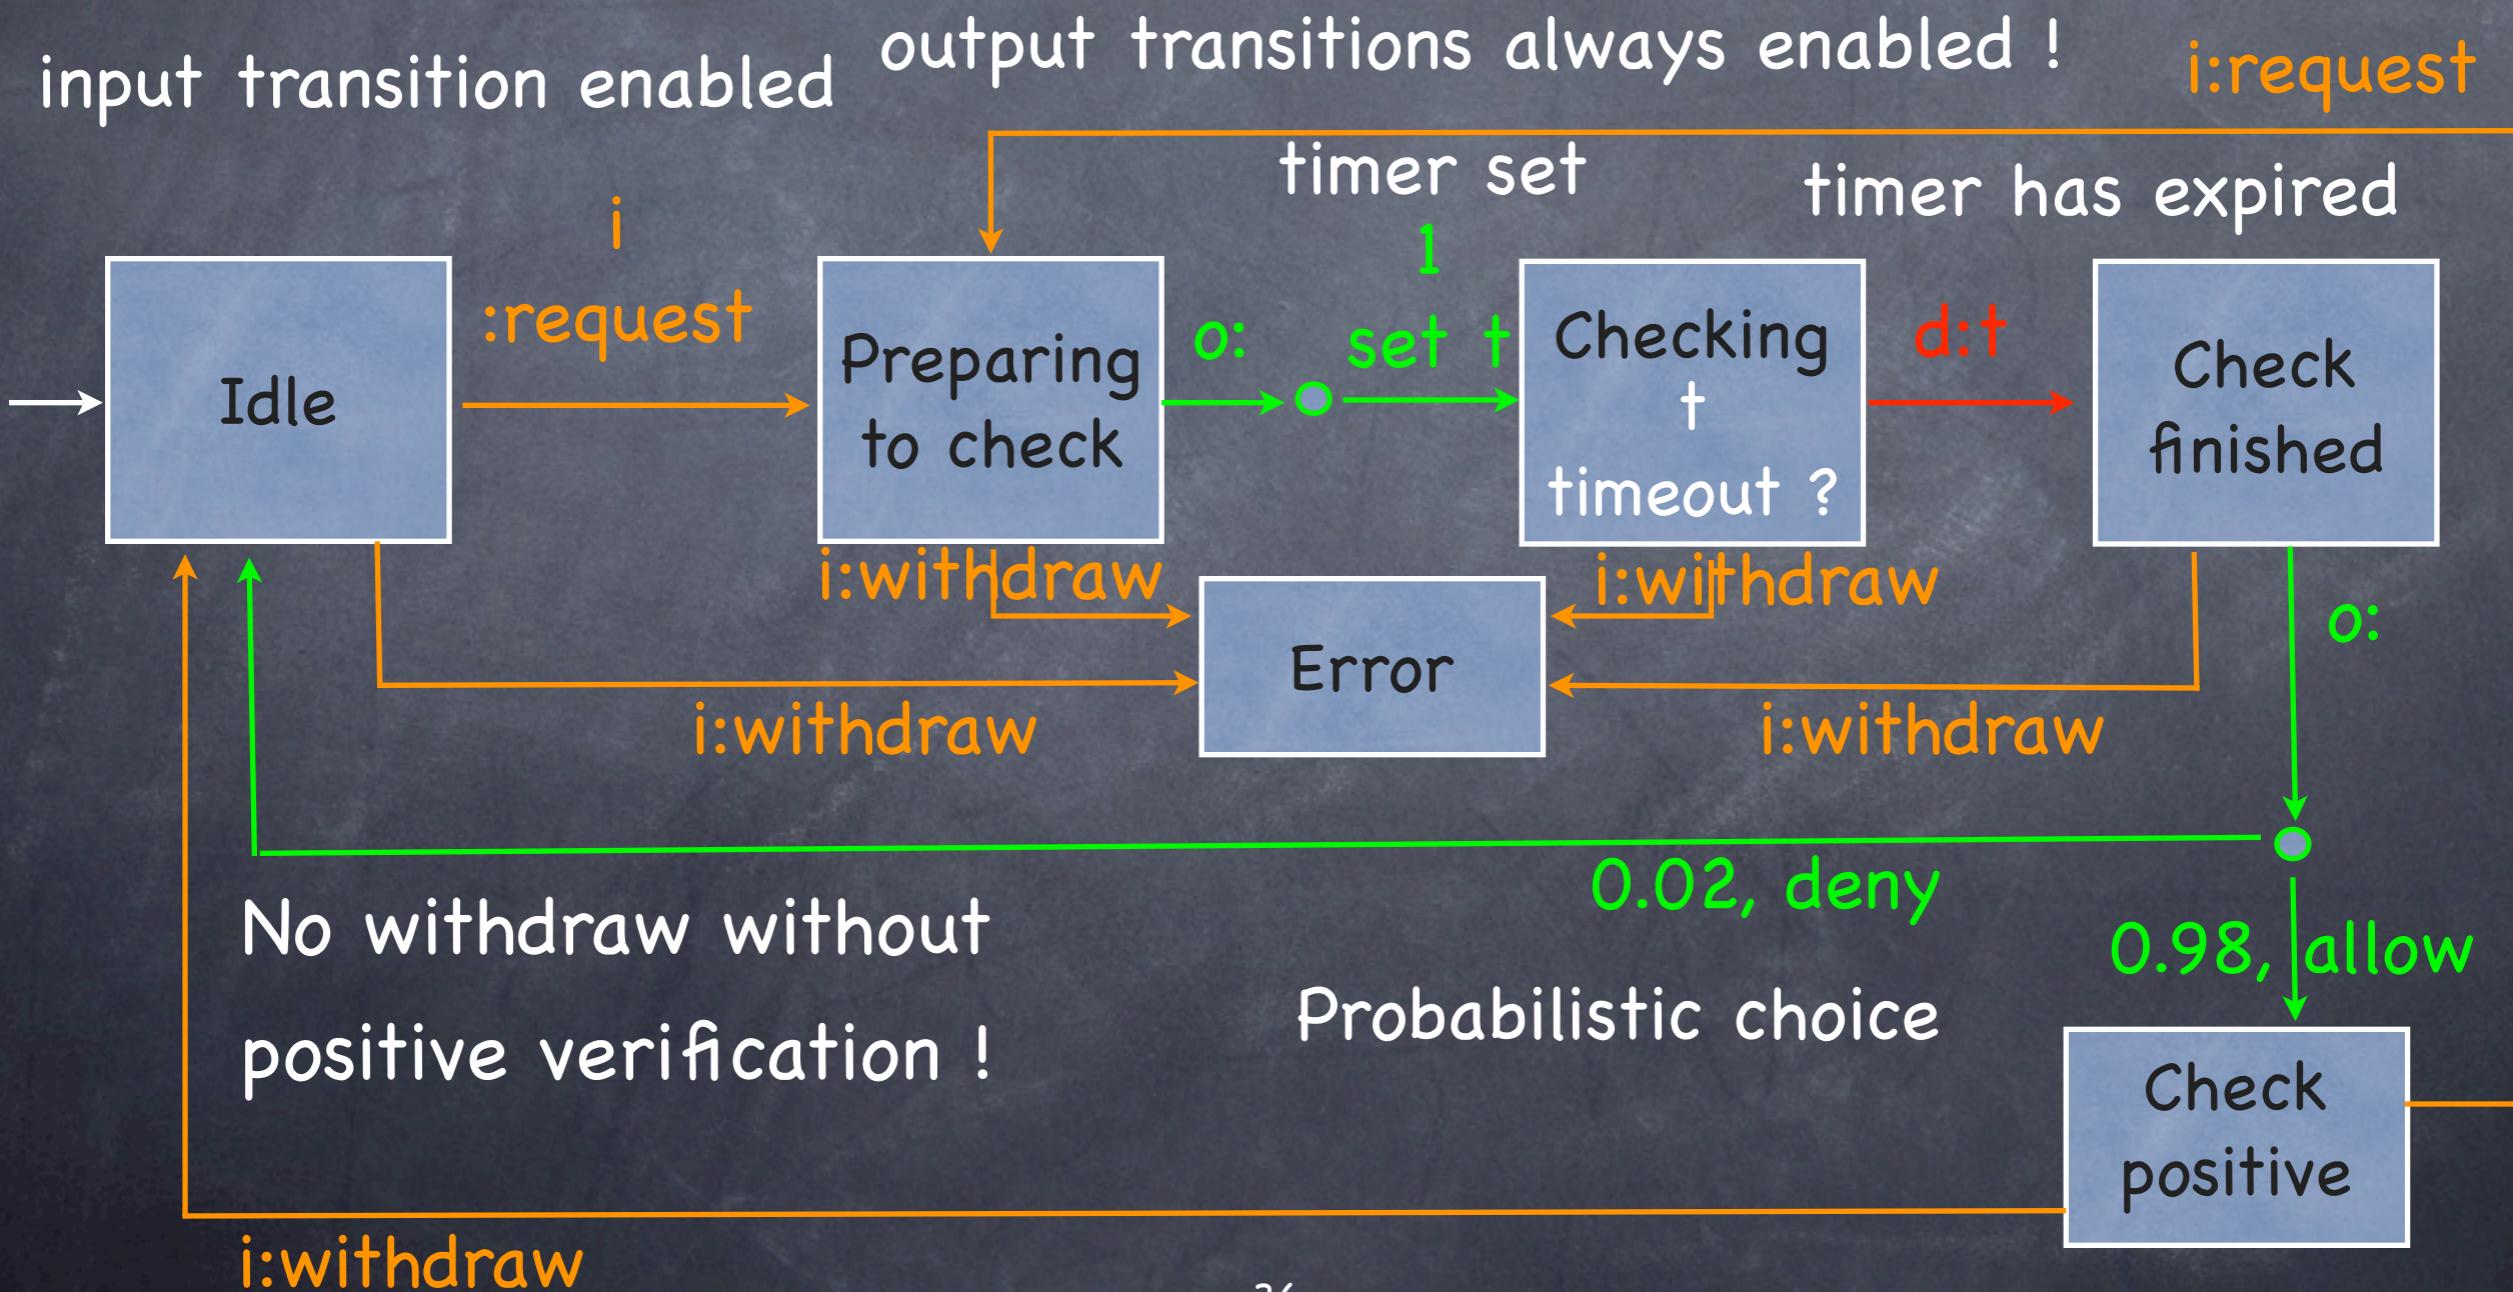

Transition	Enabled
<i>o</i>	Always
<i>i</i>	Only if Input action present (Input enabledness)
<i>d</i>	Only if timer expires (reaches zero)

# A semantical perspective - IO-SA example

o: output transition, i: input transition  
d: delay transition

Bank behavior being modeled !

# Overview

- ⦿ An introduction to Statecharts
- ⦿ StoCharts
- ⦿ QoS Extensions
- ⦿ Syntax
- ⦿ Semantics
-  **Case Study: A Beverages dispenser**
- ⦿ Conclusion

# A beverage dispenser - Intuition

How does it work ?

- ⦿ Drinks offered ?
  - ⦿ “Espresso” coffee and “oolong” tea.
- ⦿ Payment ?
  - ⦿ Money chips - 1 Chip per drink.

# A beverage dispenser - Modeling perspective

What are we modeling ?

The behavior of the system (system randomness), as seen by the customer.

What we are **not** modeling

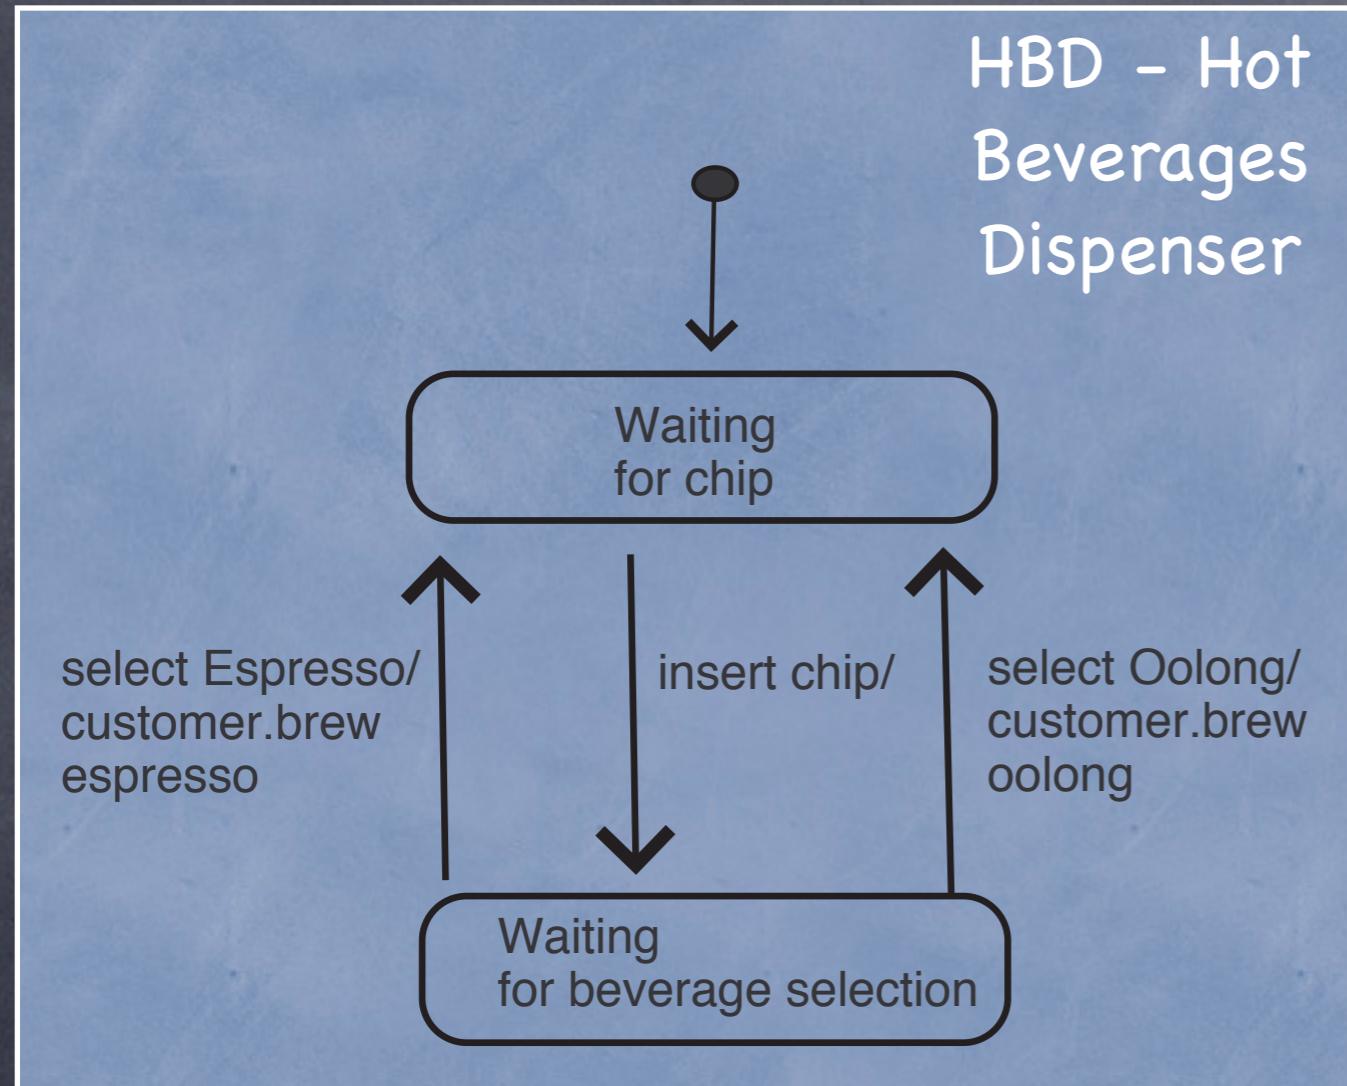

The expected/desired behavior of the customer (environmental randomness) is **NOT** being considered here.

## A naive UML Statechart - Events

- Events are sent from the customer to the HBD.
  - insert chip.
  - select espresso.
  - select oolong.

HBD = Hot Beverages Dispenser

# A naive UML Statechart - Closer look

- ⦿ **insert chip/:**

Intuition: In the event of a chip being inserted, the system evolves to its next state

- ⦿ **select oolong/customer.brew oolong:**

Intuition: In the event that oolong is selected, send the event “brew oolong” to the customer

- ⦿ Analog for espresso

# An improved UML Statechart - Closer look

What's wrong with our **naive** design ?

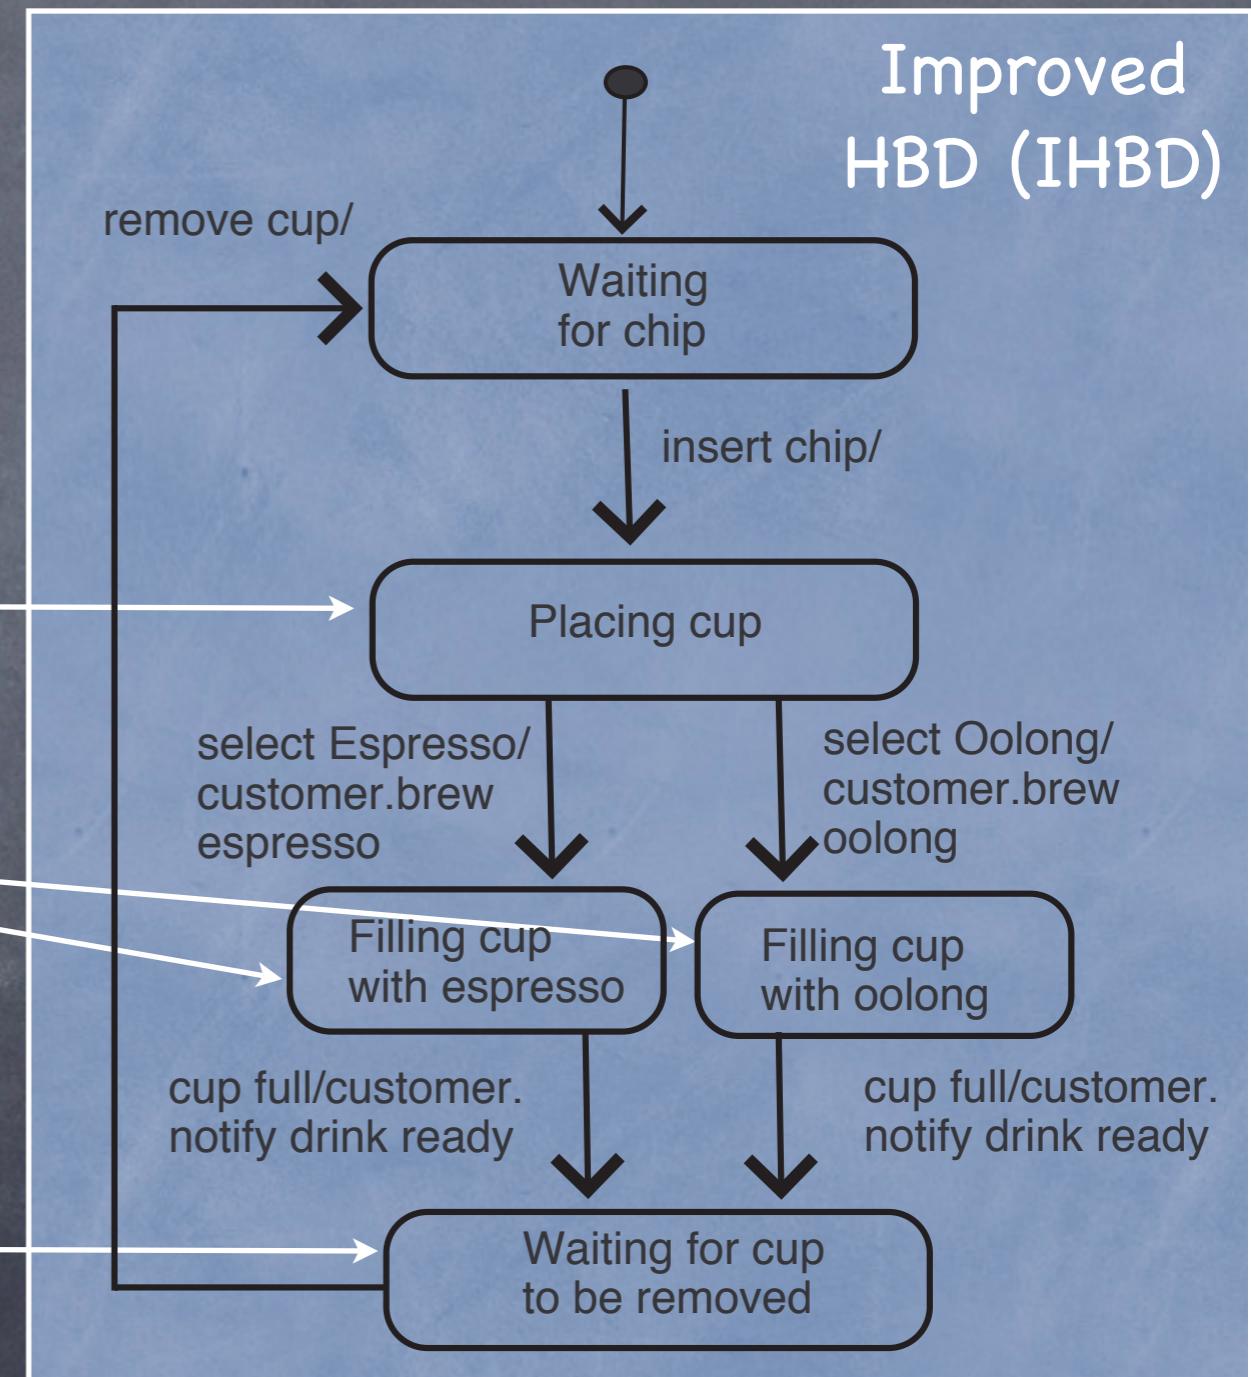

- Incomplete - Drinking what we paid for ?

- Completing the model

- “Placing” of cups in cup holder

- “Filling” of the cups

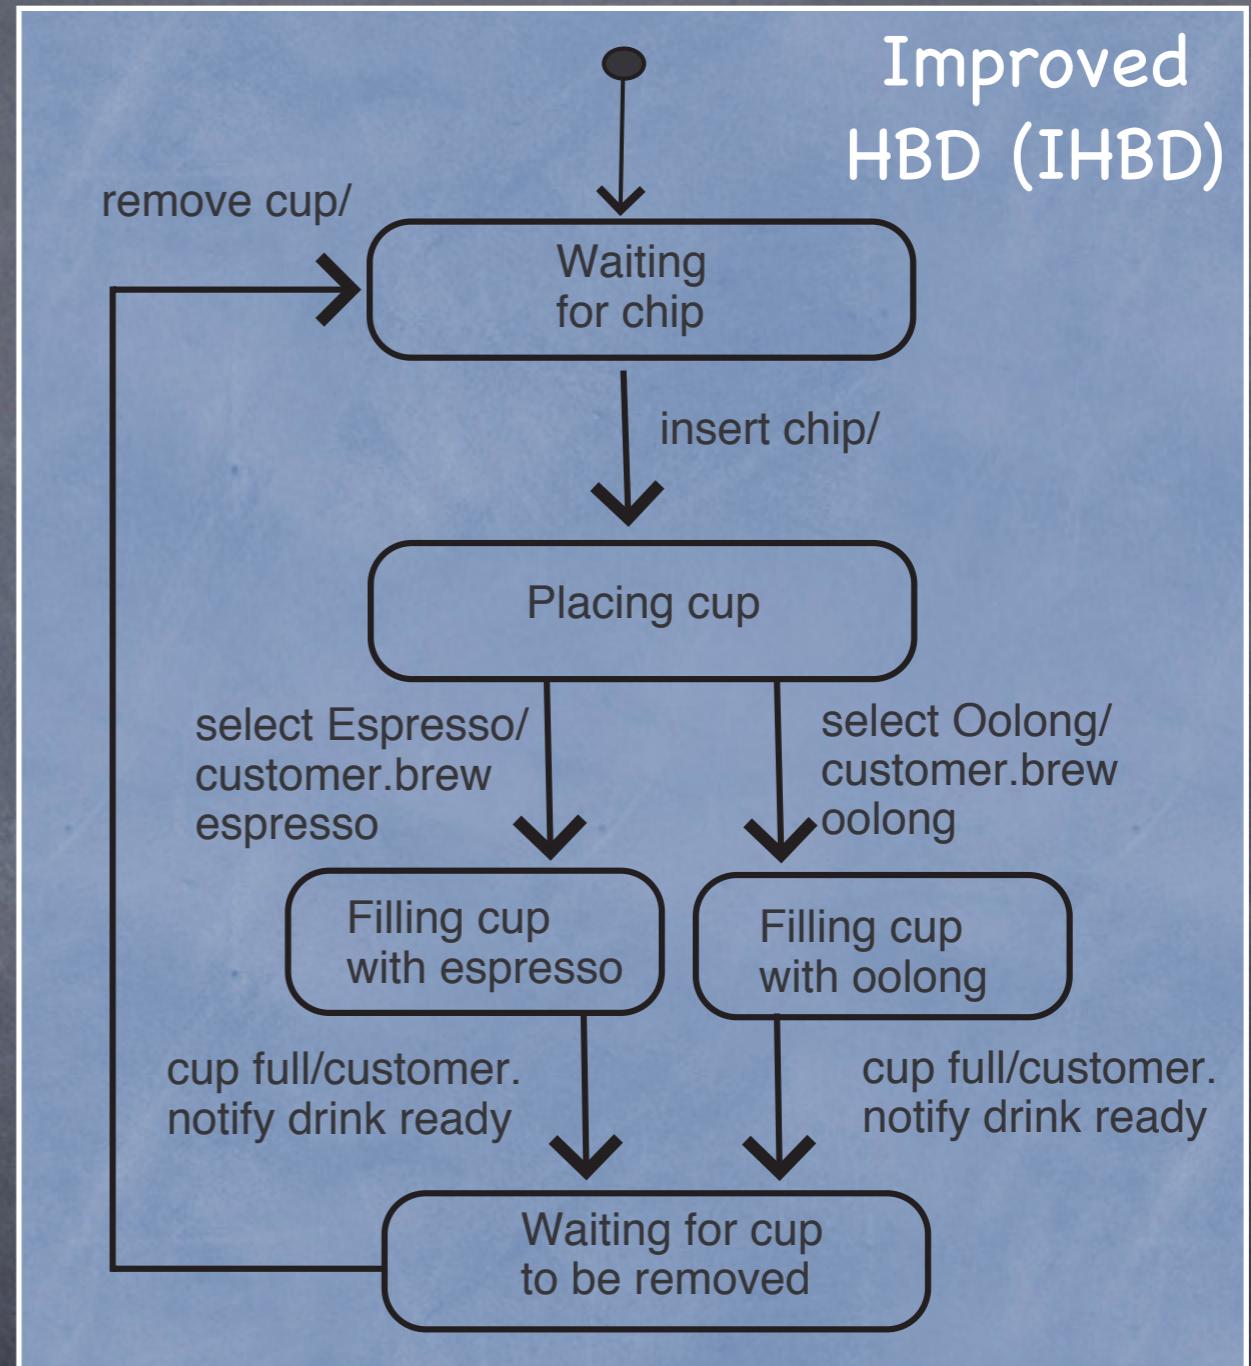

- “waiting” for someone (not a system) to remove the cup

# Extending UML Statecharts - UML Limitations

## Limitations of the IHBD

- ⌚ Modeling system requirements ?
- ⌚ (1) No cups => coin returned to customer
- ⌚ (2) Return a chip **exactly** after 10 seconds ("timeout")
- ⌚ (3) Brewing takes **about** 5 seconds ("timeout")

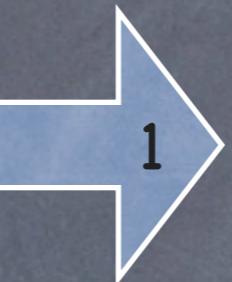

**Realisation:** Impossible to model our requirements without extensions !!!

# Extending UML Statecharts - Modeling requirements

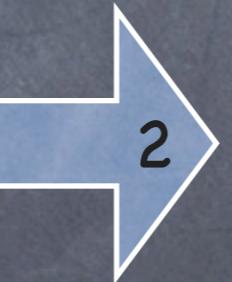

## Requirements to be modeled

- (1) No cups => coin returned to customer
- (2) Return a chip **exactly** after 10 seconds ("timeout")
- (3) Brewing takes **about** 5 seconds ("timeout")

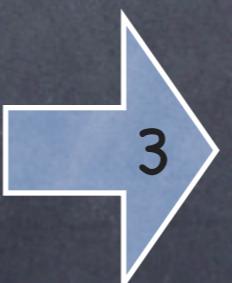

IHBD extended  
(probabilistic choice & stochastic timing)

"Probabilistic choice"  
Enough cups vs not enough cups

"Stochastic timing"  
after(DET [10s] ) /  
customer.return chip

"Stochastic timing"  
after(EXP [5s] ) /  
customer.notify drink ready

# Extending UML Statecharts – Birth of a StoChart

## Requirements to be modeled

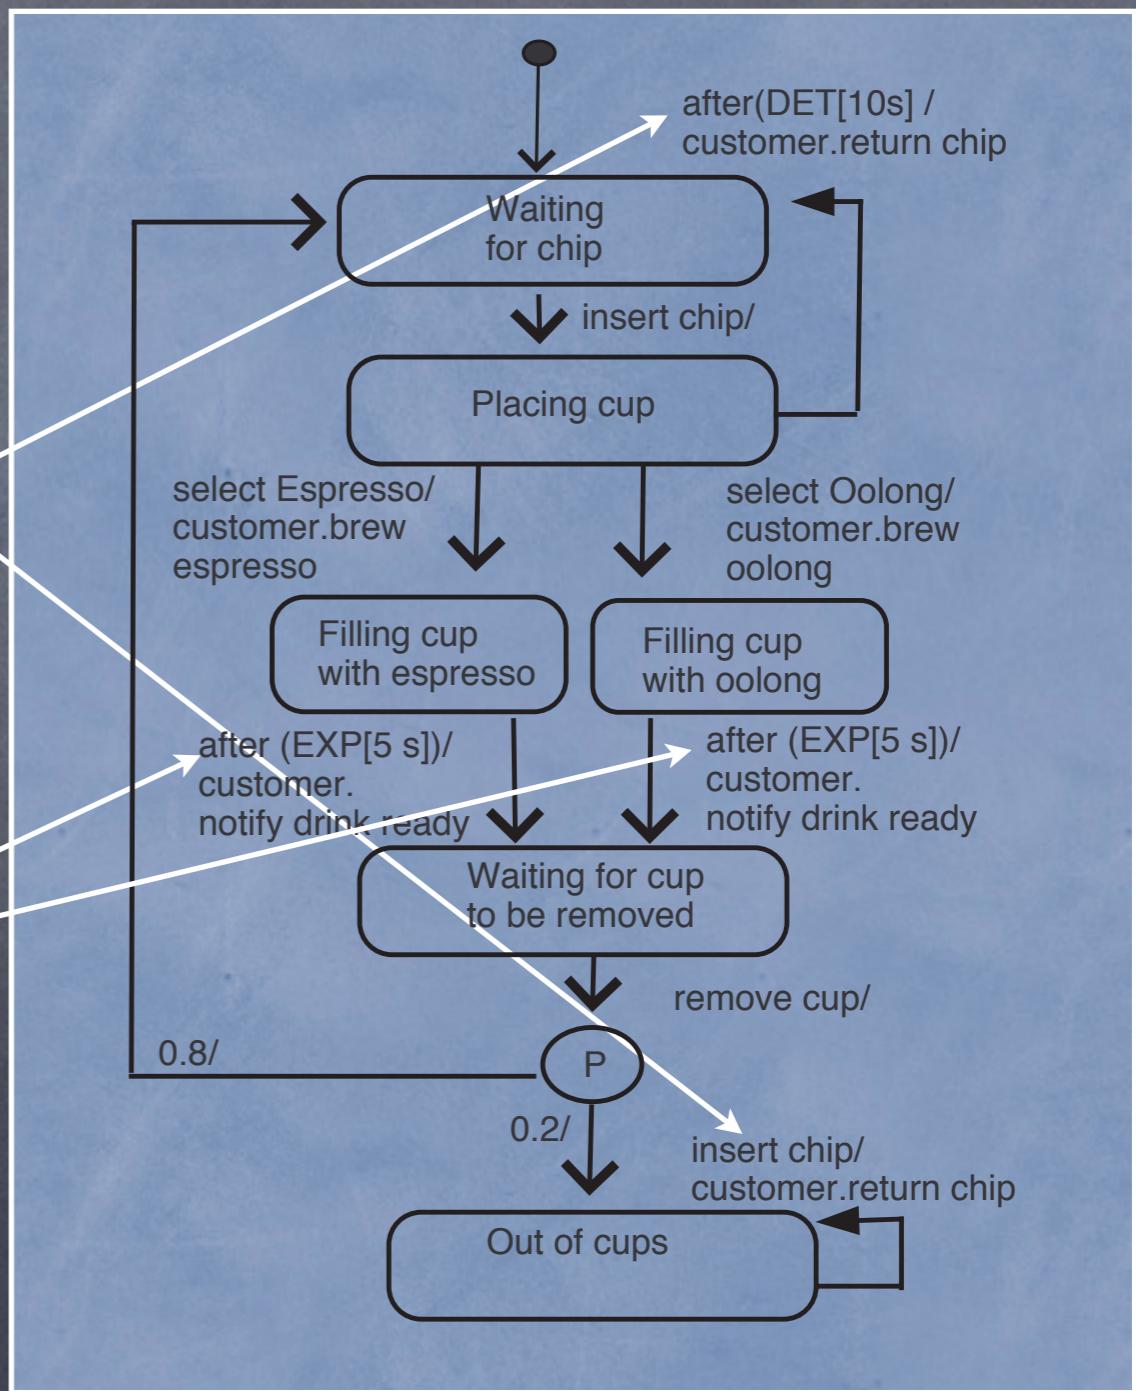

- (1) No cups => coin returned to customer
- (2) Return a chip **exactly** after 10 seconds ("timeout")
- (3) Brewing takes **about** 5 seconds ("timeout")

(1)

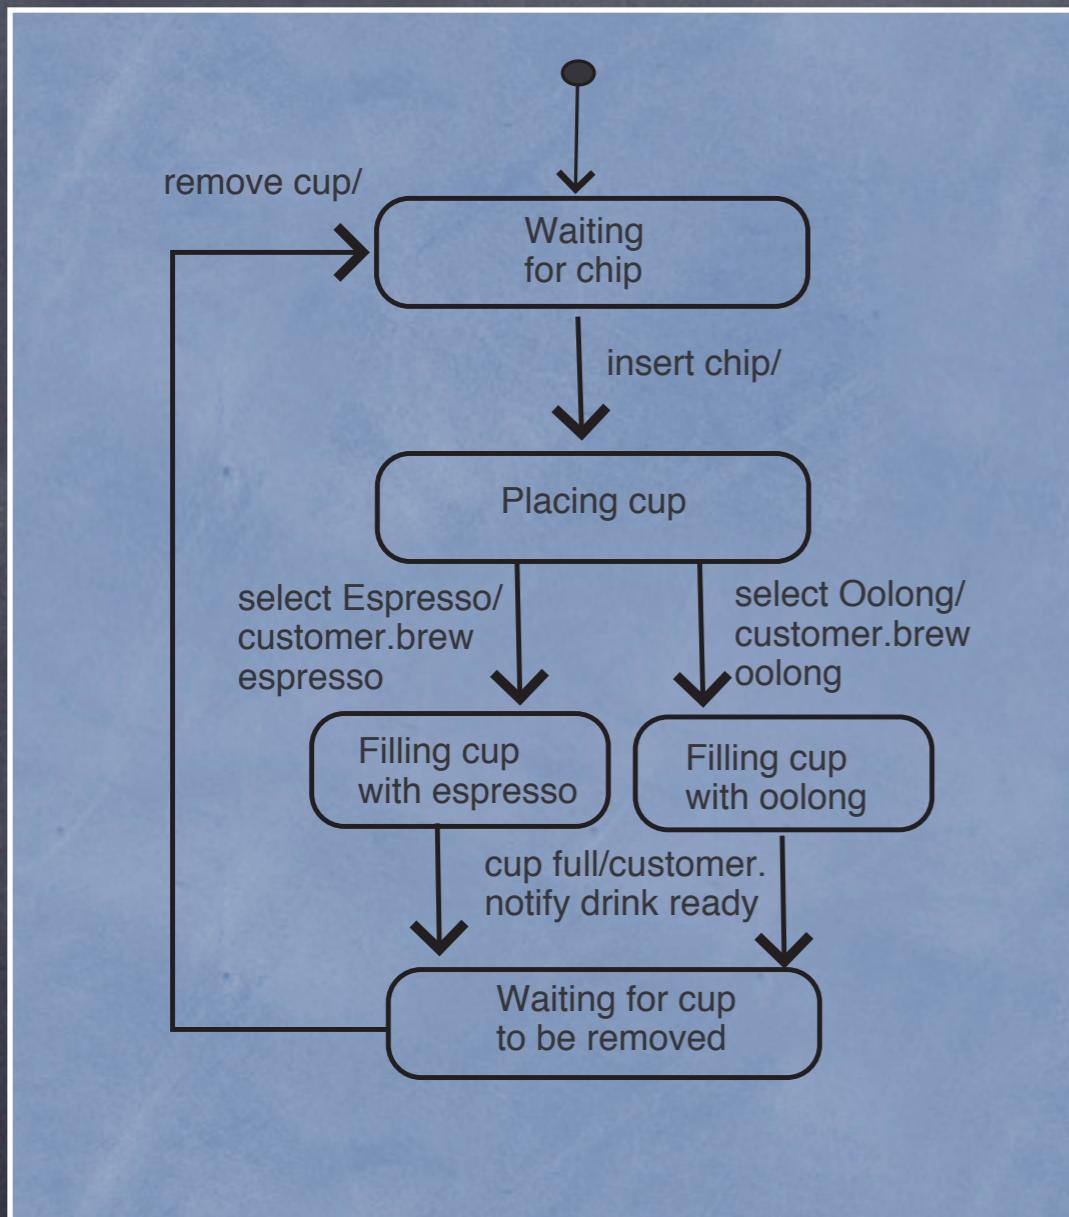

(2)

(3)

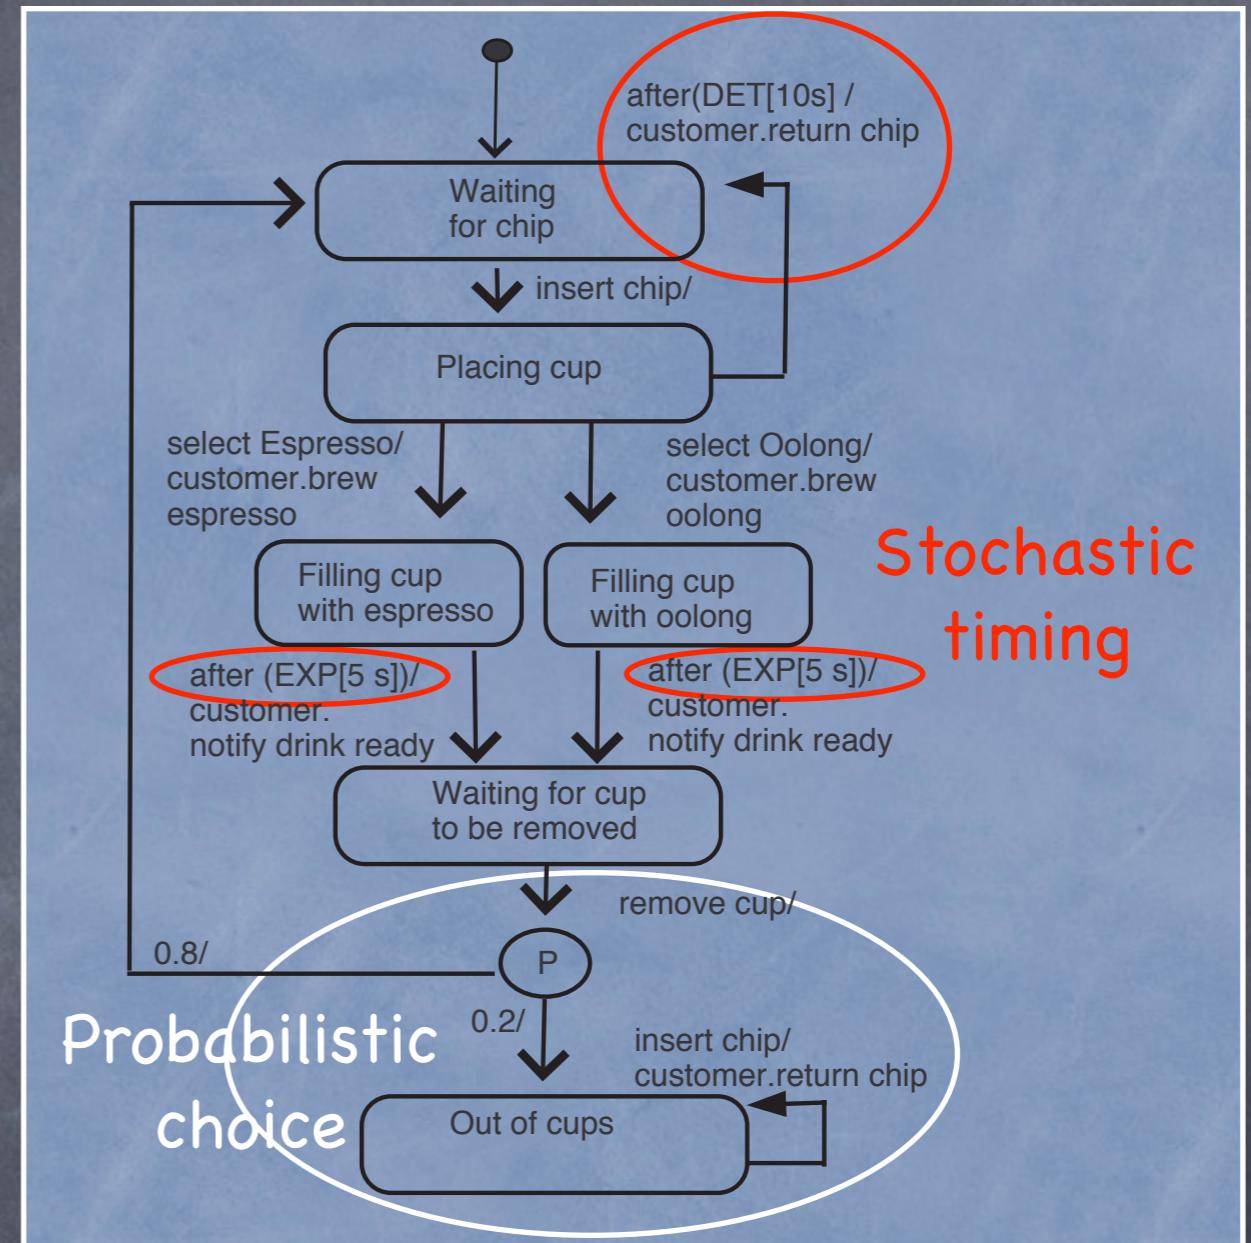

## Stochastic IHBD (S-IHBD)

# Extending UML Statecharts - Statecharts compared

IHBD - without extensions.  
 Modeling requirements  
 involving Stochastic behavior  
 not possible !

S-IHBD (IHBD with extensions).  
 Modeling requirements  
 involving Stochastic behavior  
 now becomes possible !!

# Overview

- ⦿ An introduction to Statecharts
- ⦿ StoCharts
  - ⦿ QoS Extensions
  - ⦿ Syntax
  - ⦿ Semantics
- ⦿ Case Study: A Beverages dispenser

Conclusion

## What have we learnt ?

- Awareness of **real** UML limitations and the need to extend them.
- Extending UML Statecharts with :
  - Probabilistic choice (**P-Statecharts**).
  - Stochastic timing (**StoCharts**).
- Informal and formal syntax of StoCharts ( with examples ).
- Informal semantics : Stochastic Input/Output Automata (**IOSA**).
- Application of UML extensions: Case study of beverage dispenser.
